1 Sets

Definition: A set is a collection of objects, called the *elements* or *members* of the set. We write $x \in X$ if x is an element of the set X and $x \notin X$ if x is not an element of X .

Two sets $X = Y$, if

$$x \in X \iff x \in Y$$

(“iff” or “ \iff ” both mean “if and only if”).

The empty set is denoted by \emptyset , that is, the set without any elements. X is *nonempty* if it has at least one element.

We can define sets by listing their elements:

$$X = \{a, b, c, d\}.$$

We can also have infinite sets, for example:

$$\mathbb{N} = \{1, 2, 3, \dots\}, \quad \mathbb{N}_0 = \{0, 1, 2, 3, \dots\},$$

$$\mathbb{Z} = \{\dots, -3, -2, -1, 0, 1, 2, 3, \dots\}, \quad \mathbb{Q} = \left\{\frac{p}{q} : p, q \in \mathbb{Z}, q \neq 0\right\},$$

$$\mathbb{R} = \{\text{all numbers with decimal expansions}\}.$$

1.1 Subsets

A is a subset of a set X or A is included in X , written $A \subseteq X$, if every element of A belongs to X . A is a proper subset of X , written as $A \subset X$, when $A \subseteq X$, but $A \neq X$.

Def.: The power set $\mathcal{P}(X)$ of a set X is the set of all subsets of X .

Ex.: $X = \{1, 2, 3\}$, then $\mathcal{P}(X) = \{\emptyset, \{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}\}$

The power set $\mathcal{P}(X)$ of a set X with $|X| = n$ elements has $|\mathcal{P}(X)| = 2^n$ elements because, in defining a subset, we have two independent choices for each element (does it belong to the subset or not?). Thus, the notation $2^X = \mathcal{P}(X)$ is also in use.

1.2 Set operations

The intersection $A \cap B$ of two sets A, B is the set of all elements that belong to both A and B . Two sets A, B are said to be disjoint if $A \cap B = \emptyset$; that is, if A and B have no elements in common.

The union $A \cup B$ is the set of all elements that belong to A or B . Note that we always use ‘or’ in an inclusive sense, so that $x \in A \cup B$ if x is an element of A or B , or both A and B . (Thus, $A \cap B \subseteq A \cup B$.)

The set-difference of two sets B and A is the set of elements of B that do not belong to A , that is $B \setminus A = \{x \in B : x \notin A\}$. If we consider sets that are subsets of a fixed set X (called the universe) that is understood from the context, then we write $A^c = \bar{A} = X \setminus A$ to denote the complement of $A \subseteq X$ in X . Note that $(A^c)^c = A$.

The Cartesian product $A \times B$ of sets A, B is the set whose members all possible ordered pairs (a, b) with $a \in A, b \in B$, thus $A \times B = \{(a, b) : a \in A, b \in B\}$ and $|A \times B| = |A||B|$.

1.3 Algebraic properties

Intersection is a commutative operation $A \cap B = B \cap A$; and an *associative* operation, that is:

$$(A \cap B) \cap C = A \cap (B \cap C), \text{ thus } = A \cap B \cap C$$

both are also true for the union $A \cup B$. Intersection distributes over union and union distributes over intersection:

$$A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$$

$$A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$$

We have De Morgan's laws:

$$(a \cup B)^c = A^c \cap B^c \text{ and } (A \cap B)^c = A^c \cup B^c$$

Arbitrary many unions and intersections: Let \mathcal{C} be a collection of sets. Then

$$\bigcup \mathcal{C} = \bigcup_{A \in \mathcal{C}} A = \{x : x \in A, \text{ for some } A \in \mathcal{C}\}$$

$$\bigcap \mathcal{C} = \bigcap_{A \in \mathcal{C}} A = \{x : x \in A, \text{ for all } A \in \mathcal{C}\}$$

1.4 Relations

Any subset of the Cartesian product of two sets X, Y defines a (binary) relation $R \subseteq X \times Y$ between these two sets. Given $(x, y) \in R$ we may denote this inclusion simply as xRy . Notation: \forall means 'for all', \exists means 'exists'. A binary relation R is *univalent* if

$$\forall x \in X, \forall y \in Y, \forall z \in Y \text{ we have } (x, y) \in R$$

A binary relation R is *total* if

$$\forall x \in X, \exists y \in Y \text{ we have } (x, y) \in R$$

Def.: A partially defined function is a univalent binary relation, and a function is a univalent and total binary relation. Thus a function $f : X \mapsto Y$ is defined by a univalent and total $xRy \iff y = f(x)$. The set of all functions from X to Y is commonly denoted as

$$Y^X = \prod_{x \in X} Y$$

1.5 Orders and equivalences

Def.: An order \leq on a set X is a binary relation on X , s.t. for every $x, y, z \in X$:

1. $x \leq x$ (reflexivity),
2. If $x \leq y$ and $y \leq x$ then $x = y$ (antisymmetry),
3. If $x \leq y$ and $y \leq z$ then $x \leq z$ (transitivity).

An order is *linear* or *total* if $\forall x, y \in X$ either $x \leq y$ or $y \leq x$. If \leq is an order, then we define a strict order by $x < z$ if $x \leq y$ and $x \neq y$.

If for a relation \sim in 2. instead of antisymmetry we have *symmetry*: If $x \sim y$ then $y \sim x$ then \sim is called an equivalence relation.

2 Functions

Per definition a function $f : X \mapsto Y$ is a univalent and total relation, that is for every $x \in X$ there is a unique $y = f(x) \in Y$. $Do(f) = X$ is called the *domain* of f , and $Ran(f) = \{y \in Y : \exists x \in X, y = f(x)\} \subseteq Y$ is called the range of f . Also $f(A) = \{y \in Y : \exists x \in A, y = f(x)\}$ for some $A \subseteq X$.

Ex.: The identity function $id_X : X$ on a set X is the function that maps every element of X to itself, that is $id_X(x) = x$ for all $x \in X$.

Ex.: the characteristic or indicator function $\chi_A : X \mapsto \{0, 1\}$ of $A \subseteq X$ is defined as

$$\chi_A(x) = \begin{cases} 1, & x \in A, \\ 0, & x \notin A. \end{cases}$$

The graph of a function $f : X \mapsto Y$ is defined as

$$G_f = \{(x, y) \in X \times Y : y = f(x)\}$$

2.1 Properties of functions

A function $f : X \mapsto Y$ is

1. injective (one-to-one) if it maps distinct elements to distinct elements, that is $x_1, x_2 \in X$ and $x_1 \neq x_2$ implies that $f(x_1) \neq f(x_2)$,
2. surjective (onto) if its range $Ran(f) = Y$, that is for every y there exists an x , s.t. $y = f(x)$.
3. If a function is both injective and surjective then its bijective.

We define the composition $f \circ g(z) = f(g(z))$ of functions $f : Y \mapsto X$ and $g : Z \mapsto Y$. Note that we need the inclusion $Ran(g) \subseteq Do(f)$. \circ is associative.

A bijective function $f : X \mapsto Y$ has an inverse $f^{-1} : Y \mapsto X$ defined by

$$f^{-1}(y) = x \text{ if and only if } f(x) = y$$

that is $f \circ f^{-1} = id_Y$ and $f^{-1} \circ f = id_X$.

If $f : x \mapsto Y$ is merely injective than still $f : X \mapsto Ran(f)$ is bijective, thus invertible on its range with inverse $f^{-1} : Ran(f) \mapsto X$.

2.2 Groups, monoids, fields

Def.: Given a function $f : X \times X \mapsto X$ we may denote $f(x, y) = x * y$ and consider this as a binary operation on X . For example addition of integers is such an operation. Then we say that $*$ is/has

1. Associative, if $x * (y * z) = (x * y) * z$,
2. Commutative, if $x * y = y * x$,
3. Neutral element, if there exists $e \in X$ (a neutral element), s.t. $x * e = e * x = x$,
4. Inverse elements, if for all $x \in X$ there exists $x' \in X$ called an inverse of x , s.t. $x * x' = x' * x = e$ where e is a neutral element.

Def.: $(X, *)$ is called a

1. Semigroup, if $*$ is associative,
2. Monoid, if $(X, *)$ is a semigroup and has a neutral element,
3. Group, if $(X, *)$ is a monoid and every element $x \in X$ has an inverse.

Theorem: In a group $(X, *)$ the neutral element $e \in X$ and inverse x' for any fixed $x \in X$ are unique.

Proof.: Indeed, if there would be two neutral elements e, e' , then $e' = e * e' = e$. Also assuming $x * y = e = x * z$, implies $x' * (x * y) = x' * (x * z)$, that is $y = z = x'$.

Let $(X, \cdot, +)$ be given with binary operations \cdot and $+$.

Def.: $(X, \cdot, +)$ is a field if

1. $(X, \cdot, +)$ is a commutative group with neutral element 0,
2. $(X \setminus \{0\}, \cdot)$ is a commutative group,
3. \cdot distributes over $+$ (distributivity), that is: $x \cdot (y + z) = x \cdot y + x \cdot z$. In this case $+$ is usually called addition and \cdot multiplication.

Ex.: the rational numbers \mathbb{Q} is a field, moreover an ordered field $(\mathbb{Q}, \cdot, +, \leq)$ equipped with the total order $x \leq y \iff 0 \leq y - x$, where 0 is the neutral element of $+$.

Ex.: the set of real numbers \mathbb{R} is also a totally ordered field $(\mathbb{R}, \cdot, +, \leq)$

Axiom: the \leq order of \mathbb{R} satisfies

- I. $x \leq y$ implies $x + z \leq y + z$,
- II. $x < y$ and $z > 0$ implies $xz < yz$.

2.3 Supremum and infimum

Def.: A set $A \subseteq \mathbb{R}$ is *bounded from above*, if $\exists M \in \mathbb{R}$ s.t. $x \leq M$ for all $x \in A$; and it is *bounded from below*, if $\exists m \in \mathbb{R}$ s.t. $x \geq m$ for all $x \in A$. If both holds for A , then it is bounded. ('s.t.' is short hand for 'such that')

Def.: If $M \in \mathbb{R}$ is an upper bound of $A \subseteq \mathbb{R}$ s.t. for any other upper bound $M' \in \mathbb{R}$ of A we have $M \leq M'$, then M is called the least upper bound of A , denoted as

$$M = \sup A$$

Similarly, the greatest lower bound of $A \subseteq \mathbb{R}$, if exists, is denoted by

$$m = \inf A$$

meaning $m \geq m'$ for any lower bound m' of A . If $A = \{x_i : i \in I\} \subseteq \mathbb{R}$ for an index set I , we also write:

$$\sup A = \sup_{i \in I} x_i \text{ and } \inf A = \inf_{i \in I} x_i$$

Fact: by the definition supremum and infimum of a set, if they exist, are both unique and $A \geq \inf A$ for nonempty $A \subseteq \mathbb{R}$.

Def.: if $\sup A \in A$, then we call it the maximum of A denoted by $\max A$, similarly if $\inf A \in A$, then we call it the minimum of A denoted by $\min A$.

Ex.: Let $\mathbb{R} \supseteq A = \{\frac{1}{n} : n \in \mathbb{N}\}$. Then $\sup A = 1$ belongs to A , while $\inf A = 0$ does not belong to A .

Def.: let us introduce the elements $\infty, -\infty$, so that $\infty > x > -\infty$ for any $x \in \mathbb{R}$ and define the extended real numbers as $\mathbb{R} = \{\infty, -\infty\} \cup \mathbb{R}$. If a set $A \subseteq \mathbb{R}$ is not bounded from above then define $\sup A = \infty$, and if $A \subseteq \mathbb{R}$ is not bounded from below then define $\inf A = -\infty$. Also define $\sup \emptyset = -\infty$ and $\inf \emptyset = \infty$.

2.4 (Order) Completeness

Consider $A = \{x \in \mathbb{Q} : x^2 \leq 2\}$. This set is bounded from above but has no least upper bound in \mathbb{Q} .

Def(Completeness): a totally ordered field Z is complete, if all nonempty upper bounded subsets of Z have a least upper bound in Z . We call this the least upper bound property.

Theorem(Dedekind): There exists a unique (up to $(\cdot, +, \leq)$ -preserving transformation) ordered complete field satisfying the order axioms I., II. that contains \mathbb{Q} and it is the field \mathbb{R} . Such a transformation $\phi : \mathbb{R} \mapsto \mathcal{M}$ satisfies $\phi(x + y) = \phi(x) + \phi(y)$, $\phi(xy) = \phi(x)\phi(y)$, $x \leq y \implies \phi(x) \leq \phi(y)$.

2.5 Archimedean property

Theorem(Archimedean property): If $x \in \mathbb{R}$, then there exists $n \in \mathbb{Z}$ such that $x < n$.

Proof: Suppose, for contradiction, that there exists $x \in \mathbb{R}$ s.t. $x > n$ for all $n \in \mathbb{Z}$. Then x is an upper bound of $\mathbb{Z} \subseteq \mathbb{R}$, so $M = \sup \mathbb{Z} \in \mathbb{R}$ exists. Since $n \leq M$ for all $n \in \mathbb{Z}$, we have $n - 1 \leq M - 1$ for all $n \in \mathbb{Z}$, which implies $n \leq M - 1$ for all $n \in \mathbb{Z}$. But then $M - 1$ is an upper bound of \mathbb{Z} that is strictly less than $M = \sup \mathbb{Z}$, a contradiction to $M = \sup \mathbb{Z}$ being the least upper bound.

Corollary: For every $0 < \epsilon \in \mathbb{R}$, there exists an $n \in \mathbb{N}$, s.t. $0 < \frac{1}{n} < \epsilon$.

Corollary(integer part): If $x \in \mathbb{R}$, then there exists $[x] = n \in \mathbb{Z}$ called the integer part of x , such that $n \leq x < n + 1$.

2.6 Further properties

Def(dense set): $A \subseteq \mathbb{R}$ is dense in \mathbb{R} , if for any $0 < \epsilon, x \in \mathbb{R}$ there exists $a \in A$, s.t. $x - \epsilon < a < x + \epsilon$.

Theorem(density of rationals): $\mathbb{Q} \subseteq \mathbb{R}$ is dense in \mathbb{R} .

Proof: Let $0 < \epsilon, x \in \mathbb{R}$. Then for any $n \in \mathbb{N}$ we have

$$[nx] \leq nx < [nx] + 1$$

which gives

$$\frac{[nx]}{n} \leq x < \frac{[nx]}{n} + \frac{1}{n}$$

Pick $n \in \mathbb{N}$, s.t. $0 < \frac{1}{n} < \epsilon$. Then we have

$$\frac{[nx]}{n} \leq x < \frac{[nx]}{n} + \frac{1}{n} < \frac{[nx]}{n} + \epsilon$$

which implies $x - \epsilon < \frac{[nx]}{n} < x + \epsilon$ as wanted.

2.7 Properties of sup and inf

2.8 Intervals and topology of \mathbb{R}
